

3. Project Design Phase

Streamlining IT Procurement: Automating Standard Laptop Orders with Flow Designer

Workflow architecture, trigger-action design and field mapping

3.1 Design Summary

The design uses a simple event-driven workflow: a Service Catalog request enters the flow, and the flow creates a Catalog Task with the required configuration details and assignment.

3.2 Workflow Design

Step	Design element	Configuration
1	Flow properties	Name: Standard Laptop Task; Application: Global; Run As: System user.
2	Trigger	Service Catalog.
3	Action	Create Catalog Task.
4	Input mapping	Requested Item Record → Request item; table auto-populates as Catalog Task.
5	Task fields	Short description and description: Laptop need to Configured.
6	Assignment and approval	Assignment group: Hardware; Approval: Approved.
7	Deployment	Save and activate the flow, then attach it to Standard Laptop catalog item.

3.3 Process Flow

Standard Laptop request → Approval → Service Catalog trigger → Create Catalog Task → Set description and fields → Assign to Hardware → Review task record

3.4 Data / Field Mapping

Field	Value or mapping
Request item	Requested Item Record from the trigger.
Table	Catalog Task (auto-populated).
Short description	Laptop need to Configured.
Description	Laptop need to Configured.

Field	Value or mapping
Assignment group	Hardware.
Approval	Approved.

3.5 Design Rationale

- A catalog trigger keeps the workflow connected to the service request process.
- The Create Catalog Task action provides a dedicated task for the configuration work.
- Assigning the task to Hardware makes the intended responsible group explicit.
- Using fixed descriptions gives the task a consistent purpose that can be checked later.

3.6 Design Boundary

The design reflects the settings documented in the reference PDF. No additional integrations, notifications, custom tables, or approval rules are specified in the source.
